Section C

Set1,Q11
Set2,Q20
Set3,Q22

Diagram	1
Deriving expression for E_{eq}	1 1/2
Direction of E_{eq}	1/2

$E_{+q} = Kq / (r^2 + a^2)$ and $E_{-q} = Kq / (r^2 + a^2)$

The two Electric fields have equal magnitudes and their directions are as shown in diagram

Components along dipole axis get added up while normal components cancel each other.

$$\therefore \mathbf{E} = -[E_{-q} + E_{+q}] \cos\theta \hat{r} \text{ so } E = -\frac{K2qa}{[r^2 + a^2]^{3/2}} \hat{r}$$

$$= \frac{kp}{[r^2 + a^2]^{3/2}} \quad (p = 2qa\hat{r}) = \frac{-1}{4\pi\epsilon_0} \frac{p}{[r^2 + a^2]^{3/2}}$$

\therefore Direction of electric field is opposite to that of dipole moment.

Set1,Q12
Set2,Q15
Set3,Q16

a) To find charge accumulated in capacitor C_2	1/2
b) To find the ratio of energy stored	2 1/2

a) Zero

b) We have $C_{series} = \frac{3\mu F}{3} = 1 \mu F$

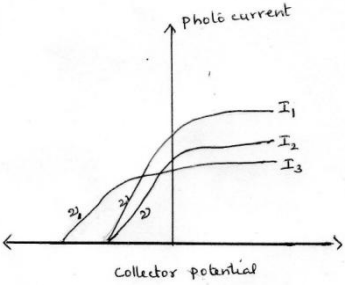

Also, $C_{parallel} = (3+3+3) = 9\mu F$

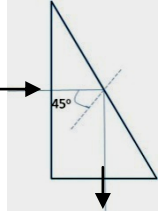

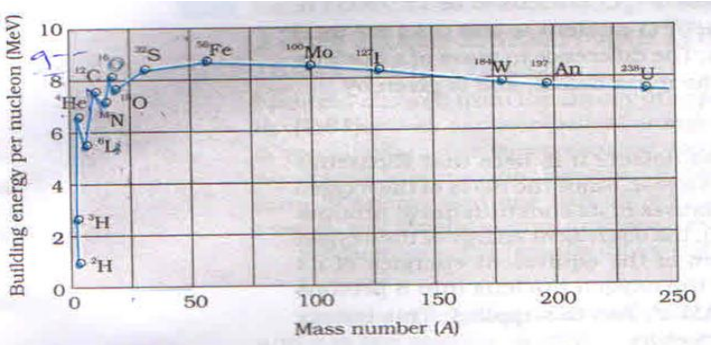

Energy stored = $\frac{1}{2} CV^2$

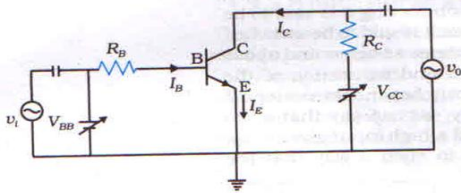

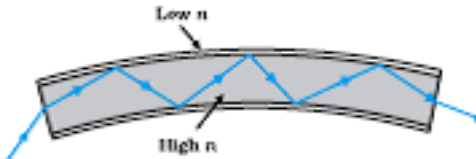

\therefore Energy in series combination = $\frac{1}{2} 1 \times 10^{-6} \times V^2$

Energy in parallel combination = $\frac{1}{2} 9 \times 10^{-6} \times V^2$

\therefore Ratio = 1:9

Set1,Q13 Set2,Q16 Set3,Q19	<div style="border: 1px solid black; padding: 5px; margin-bottom: 10px;"> <p>a) Definition of intensity 1</p> <p>b) Required graph 1</p> <p>c) Explanation of nature of the curves 1</p> </div> <p>a) Intensity of radiation equals the energy of all the Photons incident normally per unit area per unit time. a) The magnitude of the total field is obtained due to small elements

$$dB = \frac{\mu_0 n dx l a^2}{2[(r-x)^2 + a^2]^{\frac{3}{2}}}$$

x varies from $x = -l$ to $x = +l$

$$B = \frac{\mu_0 n l a^2}{2} \int_{-l}^l \frac{dx}{[(r-x)^2 + a^2]^{\frac{3}{2}}}$$

For $r \gg a$ and, we have $r \gg x$

$$B \simeq \frac{\mu_0 n l a^2}{2r^3} \int_{-l}^l dx = B = \frac{\mu_0 n l a^2 (2l)}{2r^3}$$

Here magnetic moment $m = n2l(\pi a^2)$

$$\text{Thus } B = \frac{\mu_0 2m}{4\pi r^3}$$

This is also the far axial magnetic field of a bar magnet. Hence, the magnetic field, due to current carrying solenoid along its axial line is similar to that of a bar magnet for far off axial points.

Explaining the formation of the diffraction pattern	3														
Secondary maxima	$\frac{1}{2}$														
Minima	$\frac{1}{2}$														
Why do secondary maxima get weaker in intensity	1														

The diffraction pattern formed can be understood by adding the contributions from the different wavelets of the incident wavefront, with their proper phase differences.

For the central point, we imagine the slit to be divided into two equal halves. The contribution of corresponding wavelets, in the two halves, are in phase with each other. Hence we get a maxima at the central point. The entire incident wavefront contributes to this maxima.

All other points, for which $\theta = (n + \frac{1}{2}) \frac{\lambda}{a}$, get a net non zero contribution from all the wavelets. Hence all such points are also points of maxima.

Points for which $\theta = \frac{n\lambda}{a}$, the net contribution, from all the wavelets, is zero. Hence these points are point of minima.

We thus get a diffraction pattern on the screen, made up of points of maxima and minima.

Secondary maxima keep on getting weaker in intensity, with increasing n . This is because, at the

- (i) First secondary maxima, the net contribution is only from (effectively) $1/3$ rd of the incident wavefront on the slit.
- (ii) Second secondary maxima, the net contribution is only from (effectively) $1/5^{\text{th}}$ of the incident wavefront on the slit. And so on.
