

## ★ OPERATORS

- \* operators are tokens used to perform different operations.
- \* operands are the variables or constant involved in an operation.  
Eg :-  $a + b$
- \*  $a$  and  $b$  are operands where as  $+$  is the operator
- \* Based on the number of operands required for the operation operators are classified into 3.

### 1) Unary operators.

- \* unary operator operates on a single operand.
- \* Unary  $+$  (positive) and unary  $-$  (negative) are considered as unary operators.
- \* This is used to represent sign of a number.

### 2) Binary operators

- \* Binary operators operate on two operands.  
Eg :- arithmetic operators, relational operators etc.

### 3) Ternary operators.

- \* Ternary operator operates on 3 operands.  
Eg :- conditional operators ( $?:$ )

Based on the operations operators are classified into :

#### 1. Arithmetic operators :-

- \*  $+$  (add),  $-$  (subtract),  $*$  (multiplication),  $/$  (division),  $\%$  (modulus).
- \* Modulus operator performs division operation and returns remainder as output.  $/$  (division) operator performs division operation and returns quotient as output.

## 2. Relational operators :-

- \* Relational operators are used for comparing numbers.
- \* Relational operators are binary operators.
- \* Operation using relational operator returns either true or false value.
- \* True is represented by 1 and false is represented by 0.
- \* Operators  $<$  (less than),  $>$  (greater than),  $<=$  (less than or equal to),  $>=$  (greater than or equal to),  $=$  (equal to),  $!=$  (not equal to).
- \*  $A == B$  returns true only when both the variables 'A' and 'B' has same value or else the comparison returns false value.
- \*  $A != B$  returns true when both the variables 'A' and 'B' have different values. when both 'A' and 'B' have same value the comparison returns false value.

## 3. Logical operators :-

- \* Logical operators are used to combine two or more comparison.
- \* Different logical operators includes.

### 1) Logical AND (&&) operator

- \* When both the conditions returns true value the result will be true for all other condition it returns false value.

A	B	A && B
0	0	0
0	1	0
1	0	0
1	1	1

### 2) Logical OR (||) operator

- \* This operator returns true value when any of the condition either A or B returns a true value.
- \* This operator returns false value <sup>only</sup> when both A and B returns false value.

A	B	A    B
0	0	0
0	1	1
1	0	1
1	1	1

### 3) Logical NOT (!)

- \* This is a unary operation.
- \* This operator negates the result of the relational expression.

A	!A
0	1
1	0

### 4. INPUT / OUTPUT OPERATORS

- \* C++ uses  $>>$  operator for input operation and this operator is called get from or extraction operator.
- \*  $<<$  operator is used for output operation and this operator is also called as put to or insertion operator.

### 5. ASSIGNMENT OPERATOR (=) *equal to*

- \* This operator is used to store either a value to a variable or a value stored with in a variable to another variable.  
Eg:  $a = b$ ,  $a = 5$

### 6. ARITHMETIC ASSIGNMENT OPERATORS

- \*  $+=$ ,  $-=$ ,  $/=$ ,  $*=$ ,  $\%=$  are considered as assignment operators.
- \*  $a = a + 10$  can be written as  $a += 10$  or  $a = a / 10$  can be written as  $a /= 10$  or  $a = a - 10$  can be written as  $a -= 10$ .
- \* This is also called as short hand form.

## 7. INCREMENT OPERATOR (++)

- \* This operator is used to increment a integer variable by 1 ;
- \* There are postfix increment and prefix increment.
- \* In postfix increment variable comes first following the operator. Eg:  $a++$ ;  $a = a + 1$
- \* In prefix increment operator comes first followed by the variable. Eg:  $++a$ ;

## 8. DECREMENT OPERATOR (--)

- \* This operator is used to decrement a integer variable by 1 ;
- \* There are postfix decrement and prefix decrement.
- \* In postfix decrement variable comes first following the operator. Eg:  $a--$ ;  $a = a - 1$
- \* In prefix decrement operator comes first followed by the variable. Eg:  $--a$ ;

*Important*

```
#include <iostream.h>
```

```
void main()
```

```
{
```

```
int a = 6;
```

```
cout << a++ << ++a;
```

```
cout << a-- << --a;
```

```
}
```

OUTPUT

6886

## ★ CONDITIONAL OPERATOR (?:) *important*

- \* This is ternary operator works over 3 operands.
- \* condition will be checked first using the ?: operator.
- \* When the condition returns true the statement before the :
- \* will be executed. If the condition returns false the statement after the colon will be executed.

Eg:  $x = m > 50 ? 'p' : 'f'$

- \* If the condition  $m > 50$  returns true value the variable 'x' will stored with the character 'p'. If the condition returns false the variable 'x' will be stored with the character 'f'.

## Size of OPERATOR

- \* This operator can be used to check the number of bytes allocated for a variable or a data type or a constant.
- \* size of (int) <sup>→ parameter/argument</sup> returns 2 as result as the int data type allocates 2 bytes of memory.
- \* size of (3.4) returns 4 as out put as the float data type will be allocated with 4 bytes of memory.

```
char a; char a;  
size of (a);      size of (a);
```

- \* The above code returns 1 as output as the variable is declared in char data type and char data type allocates 1 byte of memory.
